Abstract

Background: Several studies have examined the effects of folic acid fortification on the occurrence of orofacial clefts. This study was carried out to evaluate the impact of flour fortification with folic acid on oral clefts in Northern Iran.

Methods: In this hospital based study from March 2006 to September 2009, we screened the total number of live births at all hospitals in Golestan province in North of Iran, as well as the number of pregnancies affected by non syndromic oral clefts, per 100000 births during the periods before (March 2006 - June 2007), during (July 2007-March 2008) and after (May 2008- September 2009) folic acid fortification of flour was implemented. Non syndromic Oral clefts were defined in accordance with the International Classification of Diseases, 10th revision (ICD-10).

Results: The prevalence of oral clefting reduced from 64.2 per 100000 births before fortification to 32.2 per 100000 after flour fortification with folic acid. The preventive fraction rate of oral clefting after fortification period in comparison with before period was 49.8% (OR=0.502 95% CI 0.26-0.97, p=0.036).

Conclusion: This study showed that flour fortification with folic acid is associated with a significant reduction in the rate of oral clefting in Golestan province in Northern Iran.

Keywords: Oral clefts, Folic acid, Flour, Fortification, Iran.

Introduction

Cleft lip with or without cleft palate is one of the most common congenital anomalies of multi factorial etiology (1-3). The oral clefting rate varies from one of every 500 to 2,000 births in different parts of the world (4). The prevalence of oral clefting was reported 0.97 per 1000 (1 in 1025) birth in a hospital based study in north of Iran during 1998-2003 period (5).

Several factors including gender, race/ethnicity, geographic location, nationality, socioeconomic status, nutritional and periconceptional consumption of folic acid affect on prevalence rate of oral clefts (4-20).

Researches have shown that periconceptional folic acid consumption can reduce the occurrence of cleft lip with or without cleft palate and cleft palate alone (7-12, 21-24).

In spite of usefulness of periconceptional folic acid consumption to reduce oral clefts, many childbearing age women do not consume periconceptional folic acid. The Studies reported that less than 45% of pregnant women have consumed folic acid before conception (25, 26).

Several studies have examined the effects of folic acid fortification on the occurrence of orofacial clefts (27-33).
Considering the evidence on the role of folic acid to reduce the occurrence of Neural Tube Defects (NTDs) and also available experiences on fortification with folic acid and Based on the World Health Organization recommendations, through a national law, named Mandatory wheat flour fortification with folic acid (1.5 ppm: 150 Micro gram per 100 g flour.) was implemented in Golestan province in North of Iran since March 2006. Regarding to lack of studies on the efficacy of folic acid fortification on oral clefts in Iran, this study was done to evaluate the impact of flour fortification with folic acid on oral clefts in North of Iran.

Methods
This Population surveillance hospital-based study was performed in sixteen hospitals in Golestan province in Northern Iran. Regarding to wheat flour fortification in bread industries and beakers according to national law, all people consume of fortified flour in Golestan province. Therefore 100% of population in this province has used fortified wheat flour since 2007.

Ethical approval for the study was obtained from the ethics committee of Golestan University of Medical Sciences.

All live births (104232) were included in the study who was admitted in hospitals from March 2006 to September 2009. Golestan Province located in Northern Iran. This Province has a population of about 1.8 million and covers an area of about 20,460 square kilometers with an annual rate of more than 31000 annual deliveries. In each hospital, two members of the staff (registered nurse) have been recruited and trained to revise all births, to register and to describe non syndromic oral clefts. Types of Oral clefts registered were cleft lip, cleft palate, and cleft lip with cleft palate according to the International Classification of Diseases (ICD10). Oral clefts were approved by a pediatrician. Syndromic oral clefts were excluded from the study. The total number of births at all hospitals in Golestan province, as well as the number of pregnancies affected by oral clefting during the periods before (March 2006 –June 2007), during (July2007-March 2008) and after (May 2008- September 2009) folic acid fortification of flour were screened. Rate of oral clefts was defined as the number of oral clefts cases, divided by the total number of births.

Statistical Analysis
The prevalence rate per 100000 was estimated to evaluate the effect of flour fortification in three time intervals (before, introduction after fortification). For comparing prevalence rate between each of two times, we used preventive fraction (1-OR), Odds Ratio (OR) and confidence interval (CI) for OR. Furthermore, collected data were analyzed by SPSS version 15.0 and rates were compared with the chi-square test. P-value of 0.05 or less was considered statistically significant.

Results
Between 2006 and 2009, fifty one non syndromic oral clefting cases were recorded, of which 30 (58.8%) were males and 21 (41.2%) were females. Cleft lip with palate was the most common type of anomaly (37.3%), followed by cleft lip (33.3%) and cleft palate (29.4%).

In the period before flour fortification with folic acid, prevalence rate of oral clefts was 64.2 per 100000 live births, whereas in introduction period of fortification the prevalence was 59.8, and in the period after fortification it was 32.2 per 100000 live births.

The preventive fraction rate of oral clefting in introduction period in comparison with before fortification period was 7% [OR=0.932, 95% CI 0.48-1.82, p=0.83] (Table 1).

Also, the preventive fraction rate of oral clefting after fortification period in comparison with introduction period was 46% [OR=0.54, 95% CI 0.26 -1.12, p=0.09] (Table 2).
Indeed, the preventive fraction rate of oral clefting after fortification period in comparison with before fortification period was 49.8% [OR=0.502, 95% CI 0.26–0.97, p=0.036] (Table 3).

**Discussion**

This study has demonstrated that flour fortification with folic acid is associated with a reduction in rates of oral clefting in the North of Iran. Our study showed significant reduction in the prevalence rate of oral clefting after flour fortification with folic acid in comparison with pre-fortification period. Therefore, we suggest that difference of oral clefting rate between pre and post fortification period related to flour fortification with folic acid.

Several studies have reported non-significant reduction in the prevalence rate of oral clefting after fortified their food supplies with folic acid.

Hashmi et al study (2005) in Texas, USA reported non-significant reduction in CL/P prevalence by 3% (32). Also, Canfield et al (2005) from the National Birth Defects Prevention Network using data from multiple state registries found a significant decline (12%) in cleft palate alone (29). Yazdy study (30) with analysis of the data from birth certificates suggested that folic acid

Table 3. Comparison of pre-fortification and post-fortification of oral clefts per 100,000 live births; North Iran, 2006–2009
Folic acid fortification in the United States is associated with a significant decline (6%) in the prevalence of orofacial clefts. She reported the rate of Orofacial clefts were 85.2 per 100,000 births during the period before folic acid fortification (1990–1996) and this prevalence dropped to 80.2 per 100,000 births after folic acid fortification became mandatory (October 1998–December 2002) in the United States (PR ¼ 0.94; 95% CI: 0.92–0.96). According to Yazdy report, only non-Hispanic White mothers had a statistically significant decline in cleft prevalence following folic acid fortification (30).

Indeed, Johnson and Little (2008) in a meta-analysis of fortification studies in the United States and Canada have shown a reduction of approximately 7% and 8% in the prevalence rate of Cleft lip with or without cleft palate and cleft palate alone, respectively (34). The differences in findings of various studies can be related to nutritional habits, duration of study, data sampling and health service care.

Our results indicated that flour fortification in this area has resulted in a significant reduction in the prevalence rate of non-syndromic oral clefting among live births in North of Iran, because the bread which provided from flour is the main food in this area. Another study has indicated that the current periconceptional administration of folic acid intake in women with childbearing age is low (35).

Of course, other factors including perconceptional administration of folate and nutritional factors which is handled by health service in Golestan province may be effective on reduction of oral clefts. According to our results, we recommend this program could be implemented in addition to the consumption of periconceptional folic acid supplements in order to reduce birth defects.

**Conclusion**

This study showed that flour fortification with folic acid is associated with a significant reduction in the rate of oral clefting in Golestan province in Northern Iran.
