Abstract

Background: The burden of obesity and diet-related chronic diseases is increasing in Iran, and prevention and treatment strategies are needed to address this problem. The aim of this study was to determine the outcome, cost, safety and cost-consequence of non-invasive weight loss interventions in Iran.

Methods: We performed a systematic review to compare non-invasive interventions (cryolipolysis and radiofrequency/ultrasonic cavitation) with semi-invasive (lipolysis) and invasive (liposuction). A sensitive electronic searching was done to find available interventional studies. Reduction of abdomen circumference (cm), reduction in fat layer thickness (%) and weight reduction (kg) were outcomes of efficacy. Meta-analysis with random models was used for pooling efficacy estimates among studies with the same follow-up duration. Average cost per intervention was estimated based on the capital, maintenance, staff, consumable and purchase costs.

Results: Of 3,111 studies identified in our reviews, 13 studies assessed lipolysis, 10 cryolipolysis and 8 considered radiofrequency. Nine studies with the same follow-up duration in three different outcome group were included in meta-analysis. Radiofrequency showed an overall pooled estimate of 2.7 cm (95% CI, 2.3-3.1) of mean reduction in circumference of abdomen after intervention. Pooled estimate of reduction in fat layer thickness was 78% (95% CI, 73%-83%) after Lipolysis and a pooled estimate of weight loss was 3.01 kg (95% CI; 2.3-3.6) after liposuction. The cost analysis revealed no significant differences between the costs of these interventions.

Conclusion: The present study showed that non-invasive interventions appear to have better clinical efficacy, specifically in the body shape measurement, and less cost compared to invasive intervention (liposuction).

Keywords: Radiofrequency, Cryolipolysis, Lipolysis, Liposuction, Cost, Consequence, Systematic review, Meta-analysis.

Introduction

Obesity is commonly defined as the high accumulation of body fat due to imbalance between received and burnt calories (1). Over the past 20 years, obesity has been raised as a highly common nutritional dis-

order and the main risk factor for chronic and non-infectious diseases worldwide (2). The prevention and management of obesity are highly complicated because there is no clear and easy solution (3). A large proportion of obese individuals need help with their weight management (4). To prevent and treat obesity, there are currently different types of slimming and beauty systems of non-invasive intervention such as radiofrequency, Max-3, and cryolipolysis together with invasive and surgical interventions such as liposuction, and laser lipolysis. There are also preventive methods such as change of lifestyle and diet. The effectiveness, safety and cost-effectiveness of non-invasive and invasive interventions to treat obesity are still unclear.

Radio Frequency System is a non-invasive method, which uses ultrasound cavitation technology and radio frequency on fat tissue concurrently. This system focuses on sound waves with high energy content. In this system, heat is generated to turn the fat tissue into excessively small bubbles. As a result, the fat tissue is disposed of the body through lymphatic system. This system has significant effects on optimization of body metabolism, elimination of cellulite and contractions, and increased elasticity of the skin (5).

The Max-3 system offers a non-invasive method that is a combination of the three technologies of radio frequency, ultrasound cavitations, and LPG vacuum. The primary difference between this system and RF is the application of LPG vacuum method along with radio frequency and ultrasound methods. As a result, this system can offer increased metabolism, breakdown of fat and reduced size without applying any other method. Moreover, this method improves perfusion of blood, restores the health of the skin and stimulates fibroblast to produce collagen and elastin in the skin (5).

Cryolipolysis is a non-invasive method that can effectively eliminate fat and fat cells in a treated region. In this method, cold technology, vacuum and negative-pressure vacuum are used to reduce the size of fat and dispose of fat cells. In fact, the fat cells exposed to cold setting undergo apoptosis. Apoptosis is the programmed death of a fat cell. In this method, the thickness of fat layer decreases significantly (6).

Liposuction is an invasive surgical intervention used to treat surficial and deep subcutaneous fat, which was first used in the United States in 1982. It actually pulls out undesirable fat through small openings and without surgical incision (7).

Laser lipolysis is an invasive method. The term “lipolysis” means liquefying fat. If done by laser, this method would be called “Laser Lipolysis”. In this method, fat is liquefied, absorbed by the body, or disposed of by suction system (8).

The precise assessment of the outcome, safety and cost-consequence of these methods based on the evidence-based system is inevitable. The present study used the assessment of above-mentioned invasive and non-invasive methods to reduce the extent of local obesity and localized body fat through health technology in Iran.

Research Questions
In the present study, the authors intended to answer the following questions based on the health technology assessment protocol.

Q.1. How effective and safe are non-invasive methods in reducing weight and obesity (e.g., radio frequency and cryolipolysis) compared to semi-invasive methods (e.g., lipolysis) and invasive methods (liposuction)?

Q.2. How much do the non-invasive methods of weight reduction and slimming (e.g., radio frequency and Cryolipolysis) cost compared to semi-invasive methods (lipolysis) and invasive methods (liposuction)?

Study Objective
The aim of this study was to analyze the cost-consequence of non-invasive methods used to reduce weight (radio frequency and cryolipolysis) compared to semi-invasive methods (lipolysis) and invasive methods (liposuction).
Methods

Literature Review

In the present study, a systematic review and search were done in different databases to find the evidence for the outcome of the mentioned technologies. The section of economic evaluation was offered to examine the cost and cost-consequence. A separate review section was devoted to works on radio frequency and cryolipolysis compared to invasive and surgical interventions such as liposuction and laser lipolysis. To ensure a comprehensive review, the comments of the related specialists were obtained and considered. We consulted with a sports medicine specialist to highlight the consequences, inclusion and exclusion criteria.

On May 5, 2014, the PubMed, EMBASE, ProQuest, Science Direct, and Springer databases were searched to find related papers without language restriction. PubMed was searched with the MeSH word for “Radio Frequency”, “Ultrasonic cavitations”, “Cryolipolysis”, “Lipolysis” and “Liposuction” and this strategy was applied to other databases to increase the extensiveness of the research and find comprehensive data in gray papers. In addition, some journals on cosmetic surgeries were manually searched. The related papers were also reviewed.

The following search strategy was used to find studies:

I. Radio Frequency

((("radio"(MeSH Terms) OR "radio"(All Fields)) AND ("epidemiology" (Subheading) OR "epidemiology"(All Fields) OR "frequency"(All Fields) OR "epidemiology" (MeSH Terms) OR "frequency"(All Fields)) AND fat(All Fields)) OR ("weight loss"(MeSH Terms) OR ("weight"(All Fields) AND "loss"(All Fields)) OR "weight loss"(All Fields)) OR (("ultrasonography"(MeSH Terms) OR "ultrasonography"(all fields) OR "ultrasonic-
diofrequency. To offer a good comparison, the two interventions of laser lipolysis and liposuction were considered as alternative treatments for the existing technologies. With respect to the outcome, the mean reduction of thickness of fat layer was regarded as the primary outcome. Based on the clinical guide issued by the International Society for the Advancement of Kinanthropometry (9), the outcome of application of interventions associated with reduction of body fat was assessed through measuring the thickness of fat layer before and after intervention. In addition, the calculation of environmental changes in the treated sites was done to assess the outcome of slimming and progress in cellulite tissue through an instrument for grading cellulite removal. Of course, other outcomes such as satisfaction of the patient with progress of the treatment and the mean level of weight reduction and reduced body mass index were reviewed.

**Synthesizing Method**

Two individuals independently evaluated the titles and abstracts of all papers collected through the electronic and manual searching. Necessary measures were taken to obtain the full-text articles. The complete texts of the papers were reviewed, included or excluded based on the developed criteria. We considered “Critical Appraisal Skills Program” checklist (CASP) to quality the assessment. Although the majority of the selected studies for this review had moderate quality, the low quality of the papers was not considered as a criterion for their exclusion. To extract data, a data extraction form was designed by Excel. Two individuals extracted the data from the selected papers. In case of any disagreements, a third person evaluated the papers and made the final decision.

STATA Software (Version 10) was used to analyze the data on the consequences of reduction of abdomen circumference (cm), reduction in fat layer thickness (%) and weight reduction (kg) in studies that have the same follow-up duration.

Considering the high heterogeneity of the studies, the cumulative estimation of the effects was avoided in the economic evaluation, and cost-consequence method was used to present the result of the economic evaluation in which the outcomes were reported separately from the costs.

The analysis of the outcomes in cases where more than two studies on the outcomes existed was done by MetaINF order. In this analysis, the effect of each study on the pooled estimate of outcome was determined. In addition, the results of the meta-analysis showed the extent of modification of cumulative estimation in the case of exclusion of a study.

**Costing Method**

The costs of interventions and alternative methods were estimated in two groups of current expenses and capital expenses. In addition, two distinctive methods were used to analyze the costs from the perspective of health care providers (private health-care providing clinics) and that of the family and patients.

In the first approach, the total expenses of applying interventions were calculated in two groups of current expenses and capital expenses that service providers should pay for. In the second approach, the costs that the patients should pay to receive services were calculated. With regards to the capital expenses of the main and alternative interventions, the purchase prices for radiofrequency (THERMALIPO) were determined by the official response of Department of Medical Equipment of Iranian Ministry of Health. The prices of ultrasonic liposuction system (SmartLipo), lipolysis system (OSYRIS) and cryolipolysis (ZELTIQ) were determined by official correspondence with private clinics of cosmetic and plastic surgery. Considering the depreciation cost and the useful life of systems, the annual cost of purchasing them was calculated. In addition, the cost of a mean physical space was considered by assessing the mean rate of hiring essential space for fulfilling interventions as stated by associated physicians.
and clinics. The costs of maintaining systems, materials and supplied human forces (e.g., secretaries and technicians) as well as the overhead costs (e.g., water, electricity, etc.) were determined and included based on the specialists’ viewpoints and comments. From the patients and families’ perspective, the costs of receiving services were determined by considering the directly paid costs based on the announced tariffs of the private clinics of Iran. Considering the number of essential sessions in a complete treatment course, the total cost of this item was calculated. In addition, the indirect costs of the patients including traffic were estimated through interviews. With respect to surgical interventions, the costs of diagnostic tests and drugs as well as the mean costs of the operating room, anesthesia, visit, consultation and surgeon’s fee were calculated. It is noteworthy to mention that the costs of treating side effects were excluded due to the lack of sufficient data on the prevalence of complications after liposuction.

Economic Evaluation

As for the high heterogeneity of the outcome, the combination of cost and outcome may not be a valid ratio, so we used cost-consequence method for economic evaluation in which the outcomes were reported separately from the cost.

Results

Results of the Literature Search

Among the 3,111 papers found in systematic and manual search, 21 papers were redundant and after their exclusion, the remaining 3,090 papers were reviewed based on their titles and abstracts. Finally, 52 papers were selected for a complete text review, and 14 papers were excluded since they did not meet our inclusion criteria. The remaining 38 papers included two control studies and 36 non-randomized trial studies (i.e., comparative studies before and after intervention and without external control). Among the 36 trial studies, 10 studies examined different radiofrequency combinations (10-19) and 10 studies were about cryolipolysis intervention (20-28). Twenty-two studies out of 2,007 papers on lipolysis had the necessary conditions for further review, and finally 13 papers were included in the present study (17,29-40). With regards to liposuction, only five out of 26 studies were included in the complete text review (44-45). These studies were concerned with liposuction done by ultrasonic system and satisfied the inclusion criteria. In Flow diagram 1, the steps of systematic reviews of the main intervention are represented. The details of data extraction of the papers are represented in Tables 1-4 and Figure 1.

Statistical Analysis

Consequence

Because of different follow-up duration among included studies in different outcome group, we performed meta-analysis on nine studies with three months follow-up duration among three studies of radiofrequency, lipolysis and liposuction intervention.

Based on result, radiofrequency showed an overall pooled estimate of 2.7 cm (95% CI; 2.3-3.1) of mean reduction in circumference of abdomen after intervention, our findings revealed a moderate heterogeneity among three studies (X2=5.4, p=0.02, I2=62%). Pooled estimate of reduction in fat layer thickness was 78% (95% CI; 73%-83%) after lipolysis, our findings revealed a moderate heterogeneity among three studies of radiofrequency, lipolysis and liposuction intervention.

Based on result, radiofrequency showed an overall pooled estimate of 2.7 cm (95% CI; 2.3-3.1) of mean reduction in circumference of abdomen after intervention, our findings revealed a moderate heterogeneity among three studies (X2=5.4, p=0.02, I2=62%). Pooled estimate of reduction in fat layer thickness was 78% (95% CI; 73%-83%) after lipolysis, our findings revealed a moderate heterogeneity among three studies (X2=7.4, p=0.05, I2=72%). Liposuction showed a pooled estimate of 3.01 kg (95% CI; 2.3-3.6) of weight loss, our findings revealed a moderate heterogeneity among three studies (X2=8.1, p=0.000, I2=75%).

There is high heterogeneity of meta-analysis among all included studies in each intervention because of different follow-up duration. As a result, we performed descriptive analysis of outcome among included studies. As shown in Tables (1-4), nineteen papers reported the consequence of the mean circumferential size reduction of an organ (cm) as the main outcome. Among these papers, seven studies were related to
radiofrequency, five to cryolipolysis, two studies were about Exilis, two were about lipolysis, and three were about liposuction.

In general, the highest reduction of the circumferential size with 7.1 cm belonged to lipolysis, and the highest value in the reduction of abdomen circumference belonged to cryolipolysis.

Eight papers reported circumferential size reduction of thighs as the main outcome. In this regard, four studies on radiofrequency, two on cryolipolysis and two on liposuction were conducted. The radiofrequency intervention with 5.8 reduction of circumferential size represented the highest extent of reduction.

Nine papers suggested weight reduction as the main outcome. Among these papers, three studies on radiofrequency, two on cryolipolysis and four studies on liposuction were conducted. The highest weight reduction with 4.5 kg after intervention belonged to cryolipolysis.

Eleven studies reported the highest percentage of reduction in thickness of fat layer as the main result of the intervention. In this regard, five studies were related to cryolipolysis and the other five ones were on
lipolysis. Intervention by lipolysis with 83% reduction had the highest effect.

In association with the percentage of patients’ satisfaction, 15 studies reported this outcome as the main result of intervention. Eight studies on radiofrequency, two studies on cryolipolysis and four studies on lipolysis were conducted. It should be mentioned that 100% satisfaction after intervention was reported in one of the studies on lipolysis.

In association with the percentage of progress in treating cellulite tissue, five studies suggested this outcome as the main result of the intervention. All of these studies were conducted on the effects of radiofrequency intervention on treating cellulite tissue. Radiofrequency intervention with 100% treatment had reportedly highest level of influence as suggested in one of the studies.

The general results of the meta-analysis showed a high heterogeneity of the studies resulting from the lack of sufficient evidence on the interventions and different follow-up duration among studies. In the present study, the pooled estimation of the effects was not used in full economic evaluation analysis due to the high heterogeneity of the results, and we presented the results of the cost and outcome separately as cost- consequence analysis.

Safety

The other conclusion of the included studies was to determine the side effects of each method. In a study by Andrew on cryolipolysis (46), the patients usually observed a red color in the treated site, which disappeared in a few hours. In some cases, bruises may appear which could last for a week. A feeling of numbness may occur in some of the treated areas. The decreased nerve sensation takes one to six weeks (mean 3.6 weeks), but it is eliminated after two months. This case of reduced sensation is temporary and it does not need any intervention. Mulholland and et al., suggested certain side effects such as red skin, mild edema and severe heat in the treated area in the case of using RF system, which disappeared six hours after treatment. Leal (18) did not distinctively suggest severe side effects but mild ones such as small blisters that were attributed to the malfunction of RF system. Berankova (19) reported negligible side effects such as mild red color of surficial skin tissue at the area of the treatment, which reduced in few minutes after the end of treatment.

Cost

The results of estimating the costs of non-invasive interventions with two perspectives (the perspective of health-care providers and that of the patients and their families) are represented in the following tables. From the viewpoint of the health care providers, the costs of service provision including total current and capital expenses are annually calculated. To estimate the costs, the viewpoints of the experts of Department of Medical Equipment of Iranian Ministry of Health, plastic and cosmetic surgeons and physicians were considered.

In addition, Interviews were conducted with some patients and directors of treatment centers and private clinics. The costs are presented in Table 5. The results of analyzing costs revealed that from the perspectives of service providers, and patients and their families, radiofrequency intervention had the least cost and lipolysis had the highest.

Discussion

The increasing demand for beauty and fitness drew the attentions to using non-invasive systems in the past decade. By aiming to assess the consequence and cost-consequence of non-invasive (i.e., RF and Cryolipolysis) and invasive technologies (i.e., liposuction and lipolysis), we found that 38 out of 3,111 papers had the criteria for exclusion in the present study. In this respect, 10 studies were on different models of RF systems, 10 studies were on cryolipolysis, 13 studies were related to lipolysis and only five studies examined liposuction method through ultrasonic system. The
highest and lowest influence on the outcome of each intervention was defined based on the outcomes. The reviews of the outcomes showed that radiofrequency was more effective than semi-invasive and invasive methods in improving cellulite and reducing circumferential size of thighs. However, the alternative interventions offer better results in other factors of weight reduction and percentile thickness of fat layer.

The review of costs showed that among the interventions, radiofrequency had the least costs from the perspective of the health-care providers, and considering the acceptable consequence of this intervention in improving cellulite tissue and reducing the circumferential size of thighs, this intervention is acceptable considering cost and cost-consequence. Lipolysis had the highest cost compared to other interventions; however, it offered better results in the general outcome of reducing the circumferential size of the organs, thickness of fat layer, and satisfaction of patients than non-invasive methods. In addition, it can be concluded that compared to lipolysis, cryolipolysis is a good choice considering its acceptable results in reducing weight and circumference of abdomen and its lower costs.

**Conclusion**

Considering the significant attribution to the issue of beauty, the increasing demand of individuals to attain it, and the close association of health with interventions to achieve beauty, these systems should be used in certified medical centers and clinics. The application of these systems in bodybuilding clubs and beauty salons should be seriously prohibited. In addition, precise and proper training should be provided for using these systems, considering the exact functions of thermal settings and other essential factors. In addition, the selection of patients by health care providers should be done by certain indications because individuals whose body mass index is over 32 are not suitable for any type of intervention.
