Dear editor

We read, with great interest, a recently published review article entitled "Low birth weight in Iran: Implications from a systematic review of the literature and meta-analysis between 1999 and 2017" by Ebadi et al, which was published in the Medical Journal of the Islamic Republic of Iran (2018; 32 (1): 68-77) (1). We would like to congratulate the authors for this great review article and make some contributions.

Since 2011, to access useful and essential information on maternal and neonatal health indicators and applications for health policy and planning, the “Neonatal Health Office” and the “Bureau of Population, Family, and School Health”, in collaboration with other related offices and majority of maternity and neonatal health experts in universities, designed various questionnaires and software to record birth events in hospitals.

At first, this network was implemented as a pilot project in some medical universities. However, since April 2012, all hospitals and birth centers affiliated to medical universities of Iran began to register birth-related data in the Iranian Maternal and Neonatal Network (IMaN). Nevertheless, the network has evolved considerably since then. IMaN is one of the greatest sources of information for monitoring maternal and neonatal health. This network records almost all births (live & dead), demographics, and maternal and neonatal health information electronically in and out of hospitals across the country. Since 2014, IMaN has registered out of hospital births that have occurred at maternity and child birth facilities, homes, or other places.

In this system, such information as the demographic characteristics of the newborn's mother, relationship between parents, number of parity and gravidity, mode of delivery, abortion history, gestational weeks, mother's medical history, risk factors for pregnancy and childbirth, birth date, and infant's birth characteristics (eg. body weight) are recorded.

In this study, the prevalence of Low Birth Weight (LBW) rates was 7.3% in 2014, 7.1% in 2015, and 7.2% in 2016.

Low birth weight in Iran based on Iranian maternal and neonatal network

2016 among total births in Iran. The LBW rates among live births were 6.7% in 2014, 6.5% in 2015, and 6.6% in 2016.

However, in Ebadi et al. study, the prevalence of LBW was 8% (95% CI: 7-9) in Iran.

The difference may be due to the lack of studies on the LBW rate in different geographical areas of Iran, high heterogeneity rate, and the quality of included studies in this systematic review (1). Also, the coverage rate of IMaN throughout the country is almost more than 95%.

Conflict of Interests

The authors declare that they have no competing interests.
