Psycho-social consequences associated with COVID-19 in people with ASD and their families: A literature review

Mahta Alsadat Aarabi1, Kianoush Abdi1*✉, Mohammad Saeed Khanjani2

Received: 22 Mar 2021 Published: 7 Oct 2021

Abstract

Background: COVID-19 has become a global pandemic and has inevitably affected the whole world. This effect is greater on people with ASD (ASD) and their families. Depression, attempts to cope with change, and having difficulty interacting with others are some of the challenges people with ASD often face. The aim of this study was to review the psycho-social consequences of COVID-19 in people with ASD and their families.

Methods: This study is a Literature Review. Extensive electronic search results for the keywords ASD, COVID-19, Coronavirus, psychological, psychosocial, and consequence in Google Scholar, PubMed, Scopus, ProQuest, Science Direct, SID and Magiran in 2020, eventually provided a total of 130 articles. After reviewing the titles of the articles, we excluded 85 articles as they were duplicated and/or irrelevant. Finally, based on the inclusion and exclusion criteria, 17 articles remained.

Results: In general, the change in routine and uncertainty caused by COVID-19 have caused distress for people with ASD and will worsen their symptoms and mental health. Excessive stress worsens the mental health of caregivers, and as this burden increases, they report higher rates of social harm, depression, and anxiety that affect their daily functioning.

Conclusion: The COVID-19 epidemic affects all strata of society. People with ASD are particularly vulnerable to the psychosocial effects of this epidemic. COVID-19 increases anxiety, distress, depression, financial problems, loss of a job, and even marital conflict. Access to necessary services and transmission problems are also the result of rapid social and environmental changes.

Keywords: Autism Spectrum Disorder, COVID-19, Coronavirus, Psychological, Psychosocial, Consequence

Introduction

Autism Spectrum Disorder (ASD) is one of the most common pervasive developmental disorders, which is considered as the most complex, and at the same time, the unknown childhood disorder (1-4). It is a multifactorial neurodevelopmental disorder characterized by certain social communication features such as restricted and re-

Psychosocial consequences of COVID-19 in people with ASD

Petitive patterns in interests, behaviors, and activities (5), stereotypes and the use of perceptual and expressive languages (6). The reported prevalence of ASD is still rising in recent years, affecting almost 1 in every 54 children in the United States (7). The approximate prevalence of autism in Iran is equal to 0.1% (10 per 10,000) (8). Parenting an ASD child can be stressful (9). In fact, caring for a child with ASD is associated with more parental stress than any other disability (10).

Coronavirus disease 2019 (COVID-19) is an infectious disease caused by coronavirus. Most people infected with COVID-19 develop mild to moderate respiratory problems. The virus mainly spread through saliva droplets or nasal discharge when an infected person sneezes or coughs (11, 12). COVID-19 is the most crucial issue we face now, and it has had a significant impact on our lifestyle (13). However, children generally suffer from a milder form of the illness (14). The COVID-19 pandemic has touched all parts of society. People with mental disabilities are particularly vulnerable to the physical, psychological, and social effects of this pandemic (15). COVID-19 can also affect ASD patients; the impact of this pandemic on this group will be more significant than ordinary people (16, 17). Children and adolescents with ASD are more susceptible to the disturbing effects of the COVID-19 pandemic and quarantine on their mental health (18). Many governments have now taken more restrictive measures to prevent the spread of the disease. One of these measures is staying at home for parents and children. In this situation, caring for little children with ASD can be upsetting for families and caregivers (19). The coronavirus pandemic is changing the function of society. Environmental changes, disruption of daily activities, and lower access to services and social networks will profoundly affect ASD patients and their families, and sometimes it will devastate them (20). These children usually receive therapeutic interventions a few hours a week at home, hospitals, or private institutions with special therapists. But at present, children with ASD should not be engaged in interventions to maintain their health, prevent more parental stress and aggravation of children’s behavioral problems (19). Depression, trying to cope with change, and having difficulty interacting with others are some of the challenges ASD patients deal with most of the time. However, amidst a pandemic, these challenges are exacerbated (21). COVID-19 increases anxiety and distress in ASD patients. Adaptation to increased health recommendations and observance, social isolation, and social distance has changed the usual lifestyle of people with ASD and upset them (22). Overall, 20% of ASD patients are diagnosed with anxiety, and 11% suffer from depressive disorders (23). The further distress caused by the coronavirus pandemic means that ASD patients with a cognitive disturbance may experience worsening their mental health. Even those ASD patients, who did not have mental health problems, were at higher risk for developing them, especially anxiety (24) and depression (25). Also, uncertainty about COVID-19 and the constant flow of new information can affect ASD patients and increase their anxiety and distress (23). The coronavirus, combined with its high rates of infection and mortality, has created global psychosocial effects. The widespread fear of COVID-19, the so-called corona phobia, has led to many psychiatric manifestations in various social groups (26). It is necessary to conduct a study to determine and collect the various psychosocial consequences of COVID-19 for people with ASD due to the high prevalence and many problems compared to other people in the community and even people with other disabilities. These consequences need to be investigated in order to help improve the psychosocial condition of these people by eliminating the unfavorable psychological and social conditions that have doubly affected the lives of these people and their families. This research provided evidence for policymakers, NGO planners, individuals with ASD and their families, as well as psychological and counseling service providers to develop evidence-based protocols and interventions for this group to improve their mental health and social status in the situation of COVID-19 epidemic and even after the end of this condition.

This study aimed to review the psychological and social consequences of COVID-19 on ASD patients and their families.

**Methods**

We used a Literature review through various national and international electronic databases to identify studies that report “the psycho-social consequences associated with COVID-19 in people with ASDs”.

**Keywords**: Autism Spectrum Disorder, covid-19, coronavirus, psychological, psychosocial, consequence

**Search strategy**

We selected the relevant articles with an extensive electronic search of keywords of Autism Spectrum Disorder, COVID-19, coronavirus, psychological, psychosocial, and consequence (in the title and abstract) in international databases such as Google Scholar, PubMed, Scopus, ProQuest, Science Direct, and national databases, including SID and Magiran in 2020, given the novelty of the corona issue. I used my university subscription (the University of Social Welfare and Rehabilitation Sciences) to access the Science Direct database.

Unfortunately, no Persian study was found in the national databases. In the first stage of the search, 130 articles were found. After reviewing the titles of the articles, we excluded 85 articles as they were duplicated and or irrelevant. Finally, by examining the articles’ abstracts and considering the inclusion and exclusion criteria, 17 studies out of the remaining 45 articles were included in the study (Fig. 1). Papers were evaluated using a data extraction form, including objectives, type of study, target group, sample size, and results (Table 1).

**Search strategy syntax**

The search strategy syntax for this article, for example, in the main database that was PubMed, is as follows:

```
(((Autism Spectrum Disorder [Title/Abstract]) AND COVID-19[Title/Abstract])) OR (corona virus [Title/Abstract])) AND (psychological [Title/Abstract])) OR
```

2 http://mjiri.iums.ac.ir
Data collection
Selected articles were entered into EndNote software. After removing the duplicate titles, the remaining articles, their abstracts as well as the full text of the article were independently reviewed by two authors. Another author reviewed the results, and all the results were reviewed by all three authors. The process used to identify related articles is shown in Figure 1. The flowchart of the article search process.

Inclusion and exclusion criteria
Inclusion criteria: In this article, inclusion criteria were as follows: 1) published articles, 2) articles with full text, 3) articles published in English and Persian, and 4) only articles related to the psycho-social consequences associated with COVID-19 in people with ASDs and their parents.

Exclusion criteria were as follows: This study excluded papers that did not meet the following criteria: 1) Items that do not comply with the inclusion criteria and 2) letters to editors.

Quality assessment
A quality assessment checklist was used. It was done by 2 researchers from the authors. They reviewed each article and reported independently, and if they approved both articles, we would accept the content. But if any of them rejected the material, the third person reviewed it again.

Data extraction
The authors reviewed the final articles line-by-line and extracted key points of the articles. Parallel independent assessments were conducted to minimize the risk of errors. The extracted data were entered in an electronic data extraction form on Excel.

Results
From the remaining articles, 17 articles based on the inclusion and exclusion criteria had the necessary conditions to enter the study. The specifications of these studies can be seen in Table 1. Characteristic of the studies included in the Literature review. The most important features of the articles are the following: The geographical location of the studies was scattered in different countries. The findings of this study show that many psychosocial challenges have arisen for people with ASD during the outbreak of coronavirus. Some of these challenges include depression, stress, anxiety, behavioral changes as a result of rapid social and environmental changes, disruption of daily activities and reduced access to services.

</table>
The survey revealed a lack of support, feelings of helplessness, various challenges and needs amongst parents, which although were present before, have become more prominent during an emergency state. At the beginning of police lockdown, most parents of the children with ASD handled their children on their own, which suggests that the government needs better plans and strategies for future similar situations.

A total of 85 parents completed a survey in this study (74% mothers, 22% fathers, 4% other relatives).

An empirical Article – Quantitative

The current crisis has created an unprecedented demand for parent support. Still, it has also forced us to curtail in-person services and, instead, interact via phone and the Internet media. With simple exercises based on known principles, strategies, and kernels, behavior analysts connecting with parents online may promote positive parenting to the extent that had never happened before. We have focused on the ways to promote prosocial conduct at home by pointing out that these actions are reflections of superpowers possessed by children. But it is equally valid that parents, navigating an unprecedented situation with no lead time, are the unsung heroes of this era.

Target group: Parents
Sample size: not mentioned.

A commentary – Parental guideline

At present, the COCID-19 emergency is still representing a massive psychological overload for all individuals. Additionally, returning to the same level of activity as before the COVID-19 pandemic may not be easy. Our retrospective study did not show a significant change in our individuals’ problematic behaviors with ASD after initiation of COVID-19 restrictions. We could cautiously hypothesize that the preventive countermeasures we adopted effectively reduced distress in individuals with ASD.

Discussion

Despite the novelty of the disease and the lack of published research in this area, experts believe that COVID-19 may worsen the mental status of ASD patients, primarily due to uncertainty about the situation (17). Establishing new routines for ASD patients may create challenging behavior and resistance and increase caregivers’ stress, especially if administered suddenly and without warning (23). COVID-19 pandemic affects all parts of society. People with mental disabilities are especially vulnerable to the physical, psychological, and social effects of the pandemic (15). Excessive stress may worsen caregivers’ mental health; as this burden increases, higher rates of depression and anxiety are reported by the patients. These conditions affect their daily functioning and prevent them from providing optimal care (42). Therefore, policymakers must recognize this group’s complex needs and the psychological damages they encounter. Particular attention should be paid to this group of people, and efforts should be made to minimize and alleviate their discomfort (21). To better deal with this type of psychosocial problem of different groups of society, the government, health care personnel, and other stakeholders should develop proper models of intervention and prevention of psychosocial crises (26). The aim of this study was to investigate the psychological and social consequences of COVID-19 on ASD patients and their families. The evaluation of the published articles showed significant points.

Nisticò et al. (2020) noted that people with a high-functioning ASD in the first two months of the COVID-19 pandemic suffer more from depression, anxiety, stress, and the symptoms of post-traumatic stress disorder (PTSD) compared to the healthy control group (27). The study results by Rodriguez showed that the mental health of the children with ASD changes in crises such as this pandemic. Violence, sleep disorders, irritability, screaming, and stereotyped behaviors were the most common changes (28). In the Asbury et al. study, many families reported that COVID-19 impacted their mental health and often led to an increase in their fear and anxiety, and a few families reported increased anxiety, low mood, and stress (29). In the Bent study, parents with autistic children expressed their experiences with social skills, e-learning, transfer, structure, difficulty and the stress associated with COVID-19 during the COVID-19 pandemic (30). The Colizzi study also showed that most parents of ASD patients found the period of change, and the restrictions followed the onset of emergencies so challenging that they needed more commitment than before. Behavioral problems worsened in more than one-third of ASD patients (31). Lee et al. (2020) showed an increase in social disorders such as loss of a job, increased marital conflict, and financial instability. These increasing behavioral challenges lead to problems in parent-child interactions and stress in family relationships. Some other papers in this study also indicated that parents have experienced increased anxiety and stress and needed more support (32). Cassidy and Nicolaidis (2020) revealed the points and challenges considered for all people, especially adults with ASD. Some of them included dealing with uncertainty, changing daily routines, amassed social isolation, increased vulnerabilities, more financial and job instability; increased mental health problems, including anxiety, and challenges in managing concurrent physical health issues, increasing need for formal and informal supports and concerns about health care resources (17). Narzisi study showed that COVID-19 disrupted the routines of little children with ASD, and they were asked to respect the rules and customs which were never understandable by them (9). In Stankovich et al. study, parents of autistic children raised their concerns about pandemics and emergencies. The main challenges were related to the child’s behavior and the problems that parents encountered in receiving the necessary services and support for these children (36). The results of the Szabo et al. study showed that the current crisis had created an unprecedented demand for parental support (37). Brondino et al. also found that the loss of specific long-term interventions in this group might lead to a loss of skills, decreased positive behaviors, and an increase in incompatible behaviors (38).

The Jeste et al. study results showed that telemedicine and tele-rehabilitation are available during the COVID-19 restriction period. Also, it may provide opportunities for sustainable care and education once these restrictions are waived (39). The results of the Manning et al. study showed that during the COVID-19 crisis, ASD patients and their families report high levels of stress and disturbance in life. Most of the stress areas were related to isolation, illness, and financial problems (40).

The quarantine can be very challenging for people with ASD who react inappropriately to their daily routine changes. This change in the routine can make them suffer. That is why all of us (parents, therapists, and researchers) must be united and quickly develop new and practical routines to provide peace and security for them. Other findings suggest that the COVID-19 pandemic has become an element of fear and anxiety for people. They have higher levels of anxiety in health and chronic diseases and tend to have lower levels of hope, psychological wellbeing, and mental health. The more severe the symptoms reported in a person with ASD, the higher the amount of stress reported by the caregiver, which is also true in non-pandemic periods.

Conclusion

The most recurring psychosocial challenges in the reviewed articles are as follows: Anxiety disorders and symptoms, stress about all aspects of their life, PTSD symptoms, depressive disorder, and low level of hope. Also, the most important social consequences of this epidemic include daily management, financial problems, access to necessary services, transfer, loss of a job, increased marital conflict, increased vulnerabilities and even reduction of social skills. Other psychological consequences include sleep disorders, violence, irritability, fear, helplessness and behavioral problems such as incompatible behavior.

In general, the change in routine and also the uncertainty caused by COVID-19 cause distress in ASD patients and will worsen their primary symptoms and mental
health. Policymakers should recognize that the needs of ASD patients are different from those of the general population. Policymakers must provide more support to the mental health of ASD patients and their caregivers as the nation emerges out of its current state. In case of further outbreaks or subsequent pandemic peaks, the law should provide additional freedom and support for ASD patients. Policymakers also should protect ASD patients from catching COVID-19 (21).

Limitations
One of the limitations of this study is that other language articles are not reviewed due to the lack of proficiency in other languages.

Conflict of Interests
The authors declare that they have no competing interests.
