Abstract

Background: The Nutritional Form for the Elderly (NUFFE) is a newly developed tool. This study aimed to carry out a psychometric evaluation of the Persian version of NUFFE (NUFFE-P) among nursing home residents.

Methods: Nursing home participant's aged ≥ 60 years ($n=97$) were enrolled. The inclusion criteria were residency for at least 6 months in the nursing home, and ability to communicate. Exclusion criteria included cognitive impairment, having depressed mood, severe hearing loss, problems in upper and lower extremities also, history of hospital admission during 6 months before enrollment. Anthropometric measures, laboratory tests, three-day food intake, NUFFE-P version, Mini Nutritional Assessment (MNA), Barthel Index (BI) and Geriatric Depression Scale (GDS-15) were assessed. The relationship between the NUFFE-P and MNA scores was considered as concurrent validity.

Results: The Cronbach's alpha coefficient of NUFFE-P tool was 0.76. The intraclass correlation coefficient for the total score between two raters obtained 0.98 (CI 0.97-0.99). The correlation coefficient between the NUFFE-P and the MNA scores was -0.75 ($p<0.01$). Four factors were extracted for the NUFFE-P in an exploratory factor analyses. Sensitivity 69.8% and 100% and specificity 75.7% and 85.6% were achieved to detect elderly at medium risk (cutoff=6), and at high risk of under-nutrition (cutoff=11) respectively.

Conclusion: The NUFFE-P has sufficient psychometric properties in nutritional status screening among the Iranian elderly nursing homes residents.

Psychometric properties of the Persian version of the nutritional form for the elderly (NUFFE) in nursing home residents. *Med J Islam Repub Iran.* 2018 (30 Oct);32:105. <https://doi.org/10.14196/mjiri.32.105>

Introduction

Elderly people are at a higher risk of nutritional disturbance than younger adults because of the several alterations in mental and physical function (1). Furthermore, malnutrition is a common health problem in geriatric settings, i.e. hospitals, nursing homes, and home care (2). On the other hand, malnutrition may be associated with a high

incidence rate of morbidity and mortalities (1). Under-nourishment may also have a role in the quality of life reduction among older people, even after adjusting for the severity of comorbidities (3). The prevalence of malnourishment among elderly in long-term care services was reported to be 10% and 85%, respectively (4). The preva-

↑What is “already known” in this topic:

Nutritional assessment is an important domain of health evaluation in elderly. The Nutritional Form for the Elderly (NUFFE) is an instrument for nutritional screening that is easily applicable without special nutritional training.

→What this article adds:

The developed Persian version of NUFFE is a valid and reliable tool in nutritional screening among Iranian elderly nursing homes residents.

lence of older adults who are at risk of malnutrition among institutionalized elderly in Iran may even be higher than the mentioned report, i.e., the prevalence of malnutrition among elderly residents in nursing home of the Kahrizak Charity Foundation (KCF) was expressed to be as high as 41.3% (35.0% among elderly men and 50.3% in old women) (5).

We need to apply some reliable and valid screening tools for assessing the nutritional status among elderly residents in the long-term care settings (6). These instruments should be easy to use for nursing staffs (7) that should not take longer than 5–15 minutes (6). Furthermore, these screening tools should assess the risk factors of under-nutrition among the elderly group (7).

The Persian version of Mini Nutritional Assessment (MNA) usually is utilized for malnutrition screening in Iranian older adults similar to other countries (8, 9). This tool has several items that some of them need anthropometric measurements such as height, weight. In older people particularly those with the inability to move, anthropometric measurements are very difficult (1). A newly introduced instrument for nutritional screening in the elderly is the Nutritional Form for the Elderly (NUFFE). The original version of the NUFFE was developed in Sweden. The NUFFE is a simple instrument that could easily be applied by health providers without special nutritional training and experience. This questionnaire estimates of nutritional status by asking from elderly or their caregivers and application of NUFFE does not need to any measurement (10). The instrument can also be used for both institutionalized (6) and community-dwellers older adults (10, 11).

This study aimed to carry out a psychometric evaluation of the Persian version of NUFFE (NUFFE-P) among elderly residents in nursing homes. We hypothesized that the NUFFE-P has sufficient psychometric properties in order to be used as a nutritional screening instrument among the older Iranian population.

Methods

Study design and sample

Ninety-seven elderly residents of the Kahrizak Charity Foundation's (KCF) nursing home were enrolled in this cross-sectional study. The KCF is located in the Southern suburbs of Tehran that is the largest nursing home in Iran with more than 1000 older adult residents from a diverse ethnicity. The participants were selected randomly based on a stratified cluster-sampling framework. The wards were the clusters (there were 11 wards in KCF that older adults were living there and the sample was selected from all of these wards weight to number of residents) and the residents were stratified based on the nutritional status using the Mini Nutritional Assessment (MNA) tool that categorized to well-nourished (about 35% of the participants), at risk of under-nutrition (about 50% of the participants), and under-nourished (about 15% of the participants). Subjects with MNA score ≥ 24 considered as well nourished, subjects with scores 17-23.5 considered as at risk of under-nutrition and those with MNA score < 17 was considered as under-nourished. (8) The expert nurses

selected the elderly residents, who met the inclusion criteria. The inclusion criteria were age ≥ 60 years old, being a resident of the KCF nursing home during the last 6 months and having the ability to communicate in the Persian language. Exclusion criteria included cognitive impairment [Mini Mental State Examination (MMSE) score ≤ 22] (12), having depression [Geriatric Depression Scale-15 (GDS-15) ≥ 8] (13), severe hearing loss that could not communicate in interview (whisper test $< 12/24$) (14), having problems in upper and lower extremities such as a plastering, or amputation that made limitations in anthropometric measuring also to control the effect of acute disease on nutritional status, having a history of hospital admission during 6 months before enrollment.

The sample size was estimated 96 based on the power of 90%, $\alpha = 0.05$ and the Spearman's correlation coefficient of 0.5 between the NUFFE and MNA scores. The subjects assigned to each group according to the distribution weight of nutritional condition in KCF (48 subjects were well nourished, 34 subjects were at risk of under-nutrition, and 14 subjects were undernourished).

All steps of this study were conducted according to the Declaration of Helsinki. The research ethics committee of the Aging Research Center at the University of Welfare and Rehabilitation Sciences (UWRS) in Tehran approved this study (EC-00112). All participants signed the consent form at the beginning of the study and after the orientation session.

Translation process

After receiving permission from the developer (6), the English version of the NUFFE was translated into the Persian language based on the modified protocol of the International Quality of Life Questionnaire (IQOLA) (15). Two translators, who were professional in English language and were native in Persian, translated the English version of the NUFFE into the Persian language separately. They listed some possible conceptual translations for each item and offered choices. Then they reached an agreement on the translated items and the choices. After that, 10 educated elderly, as well as, 10 formal caregivers assessed the difficulty of the items, using a 100-mm Linear Analog Scale Assessment (LASA) which 100 indicated "extremely difficult" and zero indicated "not at all difficult". The mean difficulty scores ≤ 25 was considered acceptable (15). Two other translators rated the quality of the translation (0-100) in terms of clarity, the common language applied, and the conceptual equivalence. The quality scores ≥ 90 was considered an acceptable quality for every three domains (15). Two further translators performed a backward translation. Another English specialist compared the final backward translated instrument with the English version of the NUFFE.

Data collection

Trained nurses and a nutritionist interviewed the elderly participants in the nursing home. They used a questionnaire to gather demographic data such as age and sex, which was approved by two expert researchers.

Anthropometric measurements: Weight was measured

in the morning before the breakfast on a leverage scale to the nearest 0.1 kg. Height was measured using a special liner scale ruler that was fixed into the wall in the standing position without any footwear. If the participants were not able to stand up, the measurements were conducted using equipment which could fix the head and the feet in the supine position. The height was measured to the nearest 0.5 cm. Body Mass Index (BMI) was calculated (weight in kilograms divided by height in meters squared). A flexible tape measure was applied to measure the circumferences. Mid Arm Circumference (MAC) was measured at the midpoint of the arm between the tips of the acromion and the olecranon position. The maximum circumference around the calf was considered as a Calf Circumference (CC). These measurements were carried out on the non-dominant arm and the lower limb, unless the arm or leg was paralyzed.

Other measurements: A trained researcher evaluated some aspects of the mental and physical health status by administering the MMSE, GDS-15, and Barthel Index. MMSE is one of the most commonly used instruments to assess cognitive status among old people (16). It consists of four domains and 18 items. The maximum and minimum scales of the MMSE are 30 and zero, respectively. Higher scales indicate a better cognitive function (16). Seyedian et al. carried out the psychometric evaluation of the Persian version of the MMSE instrument (12). They reported a cut-point ≤ 22 to screen the cognitive impairment among the Iranian elderly.

GDS-15 is an instrument to screen of depression among the old population (13). The maximum scale of GDS-15 is 15, which indicates the worst mood status. This tool was utilized in Iranian older population that was reported a cut-point ≥ 8 to screen depression mood (13). The Barthel Index is an ordinal scale, which consists of 10 items that measure daily function ability, particularly in daily activities. The total score of the modified form of the Barthel Index is 100, in which a higher score indicates higher functional independence in activities of daily living (17).

Laboratory tests: Laboratory finding such as serum level of cholesterol, albumin, total protein, and hemoglobin were measured as indicators of nutritional status in older adults (18, 19). Venous blood samples as were collected by using a blood collection needle holder after at least 12 hours overnight fasting. The serum was separated from the clot by centrifugation at 6000 RPM, meanwhile, the serum specimens were stored at -70°C . Cholesterol and albumin were measured by an enzymatic colorimetric technique with an auto-analyzer (HITACHI R-V910, Japan, and Pars Azmun kits). Hemoglobin levels were measured via HYTEL 300 (France) diagnosis cell counter in whole Ethylenediaminetetraacetic acid (EDTA) blood sample.

Dietary Assessment: In order to assess the association between NUFFE score and total calorie also total protein intake, dietary intake was assessed within 3 days (20). The mean of three days' kilocalorie and protein intake were considered as criteria for nutritional status. These three days included two working days and one holiday. The dietary record describes a 24-hour intake report from midnight to midnight. This dietary record was validated in the

Iranian Household Food Consumption survey (21). A trained dietitian recorded the amount of food intake from the participants. The household dish meal sizes were converted to grams. All served food and beverages, then, were coded according to the prescribed protocol and were analyzed to the content of energy and the other nutrients by Nutritionist III software (version 7.0; N-Squared Computing, Salem, OR), which was designed for Iranian foods (22).

Nutritional assessment instruments: The NUFFE has 15 three-point ordinal scale items. The maximum total score is 30 for the worst, and the minimum total score is zero for the best nutritional condition, i.e. higher scores indicate more risk of under-nutrition. It contains three domains: dietary history (two questions; weight loss and changes in dietary intake), dietary assessment (nine questions; intake of prepared food and fluid, and difficulties to eat), and general assessment (four questions; the possibility of obtaining food products, company to meals, activity and number of medications).

The MNA is composed of 18 items relating to anthropometric measurements (BMI, MAC, and CC), questions about appetite, weight loss, mobility, psychological stress or acute diseases, neuropsychological diseases, type of dwelling, medication, pressure sores or skin ulcers, number of meals, food and fluid intakes, autonomy of feeding and self-perception of health and nutrition. The maximum score is 30. Scoring categorized the subjects as being well-nourished (24-30 points), at risk for under-nutrition (17- 23.5 points), or undernourished (<17 points). The MNA can categorize the nutrition status of the elderly well without using biochemical indicators (7). Nestlé Company translated the Persian version of the MNA (23). Some studies reported that the Persian version of this tool had relatively good validity and reliability (5, 24).

Validity and reliability assessment

For assess of face validity, three nutritionists scored each item of the NUFFE-P in terms of relevancy of each item to the domains of the nutritional status and clarifying the items in the 3-point Likert scale (1= poor, 2 = intermediate, and 3 = high). The total score of the relevancy and clarifying was equal to 45. The mean of these two scores was reported as face validity.

Criterion validity was assessed by estimating correlation coefficients between the total NUFFE-IPR score and anthropometric indices such as BMI, CC, MAC, Barthels index, serum albumin, cholesterol, hemoglobin, GDS-15, and a three-day mean of the total calorie and protein intake. A correlation coefficient ≥ 0.7 was considered as strong, 0.4-0.6 as acceptable, and lower than 0.3 measured as a weak correlation (25).

Concurrent validity was considered as the correlation coefficient between the total NUFFE-P score and the total MNA score. To measure the construct validity, an exploratory factor analysis with Varimax rotation was conducted (26). The median scores of NUFFE-P were compared between "known groups" with expected high and low scores such as those who had BMI $< 24 \text{ kg/m}^2$ vs. those who had BMI $\geq 24 \text{ kg/m}^2$ (27), who had CC $< 31 \text{ cm}$ vs. CC ≥ 31

cm (28), and who had $MAC \leq 23.5$ vs. who had $MAC > 23.5$ (29).

The internal consistency of this tool was assessed by the item-total correlation and using Cronbach's alpha coefficient. The Cronbach's alpha coefficient ≥ 0.9 was considered as excellent, $0.7 \leq \alpha < 0.9$ as good, $0.6 \leq \alpha < 0.7$ as acceptable, $0.5 \leq \alpha < 0.6$ as poor, and $\alpha < 0.5$ considered as an unacceptable internal consistency (30). The inter-raters' reliability was assessed by repeating of administration of the Persian version of NUFFE by two nutritionists over a week. The intraclass correlation coefficient (ICC) type (2, k) between the scores assigned to each item and the total NUFFE-P score by two raters among the same participants (31).

Sensitivity, specificity, and positive and negative predictive values were estimated for NUFFE-P with MNA as a criterion. Receiver Operating Characteristic (ROC) curves were constructed with MNA as a criterion in order to find suitable cut-off points to NUFFE-P for identifying individuals at medium or high risk of under-nutrition. The accuracy rate was calculated for a proportion of the participants, who were correctly nutritionally classified by the NUFFE-P based on the MNA, categorized by the total participants (multiplied by 100). Moreover, the BMI < 24 kg/m² and Albumin < 4 g/dl considered as criteria to detect of at high risk of under-nutrition by ROC curve analysis.

Statistical analyses

All analyses were considered statistically significant at $\alpha < 0.05$ level and performed by using SPSS 21 (PASW statistics data editor, Chicago). Normality of the distribution of data was assessed using the Kolmogorov-Smirnov Test. For variables without a normal distribution, Spearman's correlation coefficient was used to rely on the strength of relationships. Exploratory factor analysis was utilized to determine factors that construct of the Persian NUFFE tool. The ROC curve analysis was applied to detect the cutoff of NUFFE score based on different criteria. Internal consistency was indicated the Cronbach's alpha coefficient. Inter-rater agreement was assessed using the intraclass correlation coefficient.

Results

Ninety-seven elderly residents (49 women and 48 old men) of the KCF participated in this study. The range of the ages was from 60 to 100 years. The total NUFFE-P score ranged between 2 and 14 and its mean value was equal to 7.08 [standard deviation (SD): 3.97]. On average, participants had a calorie intakes equal to 1864.70 (SD=377.15) Kcals/day and consumptions of 56.07 (SD=10.05) grams/day protein. General characteristics of the participants are presented in Table 1.

Table 1. General characteristics of the participants (N=97)

	Total N = 97 Mean (SD)	Women N = 49 Mean (SD)	Men N = 48 Mean (SD)
Age (year)	74.01 (9.50)	76.45 (9.78)	71.52 (8.63)
BMI (Kg/m ²)	25.48 (5.90)	27.32 (6.49)	23.59 (4.57)
CC (cm)	33.20 (4.66)	33.77 (5.17)	32.63 (4.06)

Table 2. Item-to-total score correlations of the Persian version of NUFFE (NUFFE-P) (N=97)

Item No.	Item Content	Cronbach's alpha if item deleted	R Spearman's	P-value*
1	Weight loss	0.737	0.512	<0.01
2	Changes in dietary intake	0.741	0.468	<0.01
3	Appetite	0.733	0.572	<0.01
4	Intake of cooked food	0.763	0.166	0.08
5	Portion size	0.732	0.582	<0.01
6	Intake of fruits and vegetables	0.742	0.436	<0.01
7	Possibility of obtaining food products	0.740	0.456	<0.01
8	Company at meals	0.747	0.404	<0.01
9	Activity	0.745	0.403	<0.01
10	Tooth, mouth swallowing difficulties	0.746	0.390	<0.01
11	Fluid intake	0.794	-0.035	0.72
12	Gastrointestinal problems	0.743	0.425	<0.01
13	Helping to eat	0.760	0.226	0.03
14	Use number of medications	0.768	0.291	0.04
15	Difficulty to eat due to health problems	0.736	0.509	<0.01
	Cronbach's alpha for total NUFFE-P items		0.762	
	Cronbach's alpha for NUFFE-P with 13 items ^a		0.796	

^a Intake of cooked food & fluid intake were deleted. *P values < 0.05 were considered statistically significant.

Face validity

The mean score of relevancy that was assigned by the three nutritionists was 39.67 of 45 (88.15%), and the mean score of clarifying was 41.67 of 45 (92.59%).

Reliability

Internal consistency of NUFFE-P was revealed by a Cronbach's alpha coefficient of 0.76. There was a significant item-total correlation between 13 out of 15 items. After deleting the two items, "intake of cooked food" and "fluid intake", the total Cronbach's alpha coefficient increased (Table 2). Inter-rater reliability of NUFFE-P was reflected by ICC coefficient of 0.98 between the total scores in two times administrated of NUFFE-P by the two raters during one week. The ICC coefficients between two times item scores are presented in Table 3.

Criterion-related validity

Correlations between the total NUFFE-P score and anthropometric characteristics such as BMI, MAC, CC, also Barthel Index as a functional status, total calorie and pro-

tein intakes, and special laboratory indices like serum albumin, cholesterol, and hemoglobin are presented in Table 4. Only the total protein intake did not have a significant correlation with the NUFFE-P score. The strongest correlation was seen between the total NUFFE-P scores and the total calorie intake, and CC.

Concurrent validity

Spearman rank correlation between the total NUFFE-P score and the total MNA score was - 0.75 ($p < 0.01$).

Construct validity

There were significant differences between the NUFFE-P median scores as "known groups" with the expected low and high scores (Table 5).

The exploratory factor analyses revealed four factors, nutritional decline, health problem, intake problem, and other problems (Table 6). The first factor could explain 56.8% of the variance and contained the items: weight loss, amount of food intake, appetite, and portion size. The Cronbach's alpha coefficient of this factor was 0.845.

Table 3. Agreements between two raters using the Persian version of NUFFE (NUFFE-P) by interclass correlation coefficient (ICC) (2, K) (N=97)

Items	ICC	CI of Intraclass correlation coefficient

Fig. 2. ROC curve of the Persian version of NUFFE (NUFFE-P) with MNA as criterion for high risk of under-nutrition at the cut-off point 11 (area under the curve = 0.929; confidence interval 95% = 0.871 – 0.986)

Sensitivity and specificity

Using MNA as a criterion to NUFFE-P, the area under the ROC curve to detect of medium risk for under-nutrition was 0.796 (CI: 0.705 – 0.886) at the cut-off point of 6.0 (Fig. 1). The calculated sensitivity and specificity values obtained 69.8% and 75.7%, respectively for detecting those who were at medium risk of under-nutrition. To distinguish the subjects who were at high risks of under-nutrition, sensitivity was 100%, and specificity was 85.6% at the cut-off point of 11.0 (the area under the ROC curve = 0.929; CI 0.871 – 0.986) at (Fig. 2). The positive predictive values were calculated as 80.8%, and 30.3% and the negative predictive values were estimated as 60.4% and 71.4% to detect of individuals at medium risk for under-nutrition and at high risk for under-nutrition.

The total accuracy rate was equal to 59.8%. The cut-off points of NUFFE-P, for detection of high risk of under-nutrition, with serum albumin level < 4.0 g/dl and BMI < 19 kg/m² as criterions were 11.0 and 10.0, respectively (Table 7).

Discussion

This study was designed to evaluate the psychometric properties of the NUFFE-P. Our findings revealed that the NUFFE-P has sufficient evidence of reliability and validity, including sensitivity and specificity, to identify the elderly who are at a medium risk of under-nutrition and those who are at high risk of under-nutrition in nursing home settings. Thereby the hypothesis was accepted.

Based on the results, there is a good internal consistency of the NUFFE-P (30). Internal consistency in this study

Table 7. Sensitivity and specificity of the Persian version of NUFFE (NUFFE-P) for detection of high risk of under-nutrition with MNA, Albumin, and BMI as criterions

	Cut-off point	Sensitivity (%)	Specificity (%)
MNA (< 17)	11	100	85.6
Albumin (< 4 g/dl)	11	75.0	84.9
BMI (< 19 kg/m ²)	10	84.6	76.2

MNA: Mini Nutrition Assessment, BMI: Body Mass Index

was approximately equal to the levels that were reported by the Norwegian study in institutionalized elderly (6). Streiner and Norman recommend that the items which do not meet an item-total score correlation of 0.20 should be omitted from the questioner's instrument and the items with low variability be excluded from the analysis (32). The internal consistency is increased with deleting the items with low variability. In this study item 4 (intake of cooked food) and item 11 (fluid intake) had weak item-total correlation; however, we did not exclude them since the NUFFE was developed as a comprehensive instrument to reflect the number of causal factors to determine under-nutrition (33). In other words, these items conceptually had strong relationships with the nutritional status, and exclusion of them is not reasonable. In the Norwegian study (6), 13 items out of 15 items showed statistically significant correlations between 0.20 and 0.60. In the Hungarian study, the number of significant items-total correlations was less than our study. The item-total score correlations were not significant in 6 items in the Hungarian study (33). A possible explanation of this discrepancy may be due to the difference of food patterns and nutritional behaviors among the Iranian older population in this study compared to the other studies. The justification of the weak item-total correlation regarding the 'eating cooked meal/day' item in our study is the low variability due to the fact that roughly all participants in our study had at least one cooked meal per day that was served at lunch time or dinner. Another explanation for the differences in the items-total correlation (items 4 and 11) may be for the reason that most of the elderly participants in this study did not have the same concept about the word "intake" for the consumption of food or liquid.

We found a strong inter-rater reliability due to high agreement between scoring of two raters. The intraclass correlation coefficient type (2, K) that we used is one of the best methods for assessing the agreement in the ordinal data (32). Except for the fourth item (eating cooked meal/day), we found an excellent agreement between the two raters. Gao et al. have recently reported an ICC = 0.88 for the Chinese version of NUFFE (10).

Anthropometric procedures are mutual factors for evaluating nutritional status (29), and three anthropometric criteria (BMI, CC, MAC) were used to assess the validity of the NUFFE-P, meanwhile Barthel Index score, total calorie intake, total protein intake, serum albumin, and hemoglobin levels were considered as the other criteria to evaluate the criterion-related validity of the NUFFE-P. The validity was supported throughout significant correlations that were found between the total NUFFE-P scores and all those criteria, except for the total protein intake. However, we could not find any significant association between the NUFFE-P score and the total protein intake. Also a similar lack of the correlation was found between the total protein intake and the total MNA score in our study (data have not been shown). These lacks of correlations may be due to the problem in converting Iranian dish meal sizes to a quantitative measure of the nutrients.

We used the exploratory factor analysis for assessing that the Persian NUFFE is valid in terms of construction.

Several studies have utilized this method for evaluation of construct validity (26, 34). We found four components (nutritional decline, health problem, intake problem, and other problems) in the factor analysis of NUFFE-P. These components were different compared to the findings of Gombos et al., which reported six factors for the Hungarian version of NUFFE. However, the first factor was similar in our study and the other study (33). The first factor is the most important factor that could explain more than 56% of the variation. The Cronbach's alpha coefficient of the first factor was higher than the finding of the Hungarian's study (33).

Concurrent validity was confirmed with a high Spearman's rank correlation coefficient between the NUFFE-P and the MNA total scores. The same high negative correlation between the MNA and NUFFE scores was reported in the Norwegian study (6). The MNA is a well-known tool to assess nutritional status as one of the components of the comprehensive geriatric assessment. Many researchers consider the MNA as the golden standard for nutritional screening in the older adults (7). Since its high concurrent validity, NUFFE-P can be used as a good alternative for the MNA. Applying the NUFFE-P by health providers is also easier than MNA, because it does not require anthropometric measurements. Performing these measurements is usually difficult in aged groups (1).

This study had some limitations. The first was that sampling conducted in a long-term care institute (KCF) and the results had to be cautiously generalized to the general older population. Another limitation might be the small sample size of the study. Performing a simultaneous exploratory and confirmatory factor analysis needs a large data for dividing the participants into two groups, randomly, one group to explore the factors and another group for testing the reliability of the found factors by a confirmatory factor analysis (35). We found an area under the ROC curve near 0.8 regarding the medium risk of under-nutrition and higher than 0.9 concerning the high risk of under-nutrition based on the MNA categorized. Our findings, in comparison to the Norwegian study, are similar in the diagnosis of the medium risk of malnutrition but we observed a higher area under the ROC curve in terms of the diagnosis of malnutrition (6). This higher sensitivity and specificity of the NUFFE-P than the Norwegian version of NUFFE in distinguishing malnutrition may refer to the small number of the malnourished participants in our study or to different sampling frameworks of these studies. The NUFFE-P had a good sensitivity and specificity to detect of high-risk under-nutrition by the criterions serum albumin and BMI.

Conclusion

The NUFFE-P showed sufficient psychometric properties in research on the older residents in a nursing home. This instrument showed a good homogeneity and inter-rater reliability as well as a good validity. The high sensitivity and specificity values of this tool revealed that NUFFE-P can particularly detect the older people at high risk of under-nutrition.

Acknowledgment

We would like to thank Mr. Mohamad-Reza Soufnejad; deputy of the Kahrizak Charity Foundation institute in his cooperation to carrying out this project.

This study was supported by the University of Social Welfare and Rehabilitation Sciences (No. 108/4/58/62671) and the Kahrizak Charity Foundation (No. A241/1386).
