Abstract

Background: The occurrence of anosmia/hyposmia during novel Coronavirus disease 2019 (COVID-19) may indicate a relationship between coincidence of olfactory dysfunction and coronavirus disease 2019 (COVID-19). This study aimed to assess the frequency of self-reported anosmia/hyposmia during COVID-19 epidemic in Iran.

Methods: This population-based cross sectional study was performed through an online questionnaire from March 12 to 17, 2020. Cases from all provinces of Iran voluntarily participated in this study. Patients completed a 33-item patient-reported online questionnaire, including smell and taste dysfunction and their comorbidities, along with their basic characteristics and past medical histories. The inclusion criteria were self-reported anosmia/hyposmia during the past 4 weeks, from the start of COVID-19 epidemic in Iran.

Results: A total of 10 069 participants aged 32.5±8.6 (7-78) years took part in this study, of them 71.13% women and 81.68% nonsmokers completed the online questionnaire. The correlation between the number of olfactory disorders and reported COVID-19 patients in all provinces up to March 17, 2020 was highly significant (Spearman correlation coefficient = 0.87, $P < 0.001$). A sudden onset of olfactory dysfunction was reported in 76.24% of the participations and persistent anosmia in 60.90% from the start of COVID-19 epidemic. In addition, 80.38% of participants reported concomitant olfactory and gustatory dysfunctions.

Conclusion: An outbreak of olfactory dysfunction occurred in Iran during the COVID-19 epidemic. The exact mechanisms by which anosmia/hyposmia occurred in patients with COVID-19 call for further investigations.

↑What is “already known” in this topic:

Since its outbreak, 2019 novel Coronavirus (SARS-CoV-2) has been associated with a spectrum of manifestations, and the full picture of COVID-19 is not yet fully understood. Hence, the various aspects of olfactory dysfunction in COVID-19 should be identified for early detection and isolation of infected individuals.

→What this article adds:

Our findings determined a significant linear correlation between the prevalence of COVID-19 and olfactory dysfunction. In an online survey, 76.24% of the participations reported a sudden onset of olfactory dysfunction. Findings of this study could lead to the worldwide awareness of researchers to conduct further clinical studies to find any correlation between disease severity and olfactory dysfunction to complete clinical manifestations of COVID-19.

quently reported in previous studies (1, 2). Epithelial damage and central nervous system involvement have been postulated as the probable reasons, however, the exact pathogenesis remains unclear (2, 3). Generally, postviral anosmia is more common in middle-aged women (4). Coronaviruses are a large family of viruses that have been presented as the causative agents of different clinical manifestations that range from a common cold to severe and great global public health concerns such as Middle East Respiratory Syndrome (MERS-CoV) and Severe Acute Respiratory Syndrome (SARS-CoV). SARS-Cov2 is a new strain from this family, which has commenced in the world in 2019 (5, 6). The World Health Organization (WHO) has reported 167 515 confirmed cases of COVID-19 with 6606 deaths by March 16, 2020 globally (7). As the virus has newly been identified, new reports about the various aspects of the disease are released almost every day during this pandemic (6, 8). However, an update on its clinical and laboratory presentations has reported fever, respiratory symptoms, cough, fatigue, myalgia, arthralgia, and breathing difficulties as the common presentations of the confirmed cases (9).

Although olfactory loss had not been mentioned as a presentation of COVID-19 until March 17, 2020, several anecdotal reports were made by Iranian otolaryngologists regarding an outbreak of olfactory loss in social media. The first, albeit was not a peer-reviewed study, was from China reporting a frequency of 5.1% for smell loss (10). This study was designed to assess the prevalence of olfactory dysfunction in Iran during the COVID-19 pandemic as a preliminary epidemiologic study.

Methods

Measurement

An online questionnaire was developed by a board, including otolaryngologists and epidemiologists, from Ear, Nose, Throat and Head and Neck Surgery Research Center of Iran University of Medical Sciences with the cooperation of Iran Medical Council. The software incorporated into the website of Iran Medical Council for corona epidemics (www.corona.ir). The full online questionnaire, which is in Google document format (go.irimc.org/smelltest), contains 33 questions, of which 18 are about any changes in smell or taste and most of the related comorbidities, 13 about basic characteristics of participants (age, date of birth, gender, city of residence, medical history, habitual history, family history), and 2 multiple-choice questions about past medical history (asthma, diabetes, thyroid disease, hypertension, epilepsy, and Parkinson's disease). Participants were asked to report their ability to smell and taste before and during the COVID-19 disease quantitatively via 10-point visual analogue scales. Questions about olfactory and gustatory dysfunctions can be seen in the [Appendix 1](#). To check the validity of the data, the questions were cross-validated with each other. For example, if participants mentioned that they had hyposmia but pointed to the zero in the Likert scale in the questionnaire, they were excluded from the analysis. To detect and omit duplicated entries, personal information (age, gender, and location) was compared be-

fore data analysis. Furthermore, to exclude incomplete responses to the questionnaire, the records with more than 30% missing data were deleted.

Study population and clinical outcomes

This cross sectional study was conducted on 10 069 cases in all provinces of Iran from March 12 to 17, 2020. Participants were cases with decreased (hyposmia) or loss of sense of smell (anosmia) during the past 4 weeks, who voluntarily responded to the online questionnaire via the internet (go.irimc.org/smelltest). The inclusion criteria were olfactory dysfunctions in responders within the 4 weeks of the start of COVID-19 epidemic in Iran. Specific groups in the populations were underrepresented because they had less access to the internet, personal computers, or smartphones, or were disable or illiterate to use the internet.

The primary outcome of the study was olfactory dysfunction of the responders at the onset of their problem and its condition at the time of their response to the questionnaire, which was measured by closed questions and scored by Likert scale. Secondary outcomes were clinical manifestations of participants such as flu or cold symptoms before anosmia, headache that needed a pain reliever drug, nasal stiffness, fever and chills, prominent cough, orbital (periorbital) pain, facial fullness and sinus pain, rhinorrhea, dyspnea, nasal irritation, parosmia, nasal pruritus, history of hypothyroidism, otalgia, sneezing (frequent), purulent nasal discharge, history of asthma, cheeks pain, previous sinus surgery or septorhinoplasty, unilateral facial palsy, and a history of hypertension, diabetes mellitus, and hyperthyroidism.

Ethical approval

Informed consent was obtained from the participants prior to filling online questionnaire in an anonymous way and in a group (pooled) fashion. The study was approved by the ethics committee of Iran University of Medical Sciences (IR.IUMS.REC.1399.002).

Statistical analysis

Categorical variables were reported as counts and percentages and quantitative variables as means and standard deviations (otherwise mentioned). The relationship between the number of participants and the number of confirmed COVID-19 patients (from national reports) was analyzed by the Spearman correlation coefficient. This part of the assessment has been considered as an ecological study because data were not at individual level.

Results

The results are based on the reported cases of anosmia or hyposmia in an Iranian population, gathered by an online questionnaire developed by Ear, Nose, Throat and Head and Neck Surgery Research Center of Iran University of Medical Sciences in cooperation with Iran Medical Council from March 12, 2020 (15:20) until March 17, 2020 (10:32).

During this period, 15 228 people viewed the online questionnaire, of whom 10 249 reported olfactory dysfunction and answered the questions. The following participants

were excluded from the analysis: 25 participants who did not respond to more than 10 questions (from total of 36 questions), 155 duplicated records that were similar in personal information, and 8 participants in whom the duration of disease was more than 30 days. Thus, the final analysis represented 10 069 responders.

Based on demographic data, age distribution ranged from 7 to 78 years (32.5 ± 8.6), 71.13% were female and 81.68% nonsmoker.

Most responders were from Gilan (51.9%), Tehran (18.4%), Mazandaran (6.6%), Golestan (4.3%), and Qom (2.7%) provinces. Despite a significant difference in the number of responders from multiple geographical areas, the distribution of demographic and clinical variables was homogenous among different provinces of Iran.

The number of cases of anosmia was compared to the official report of patients with COVID-19 in various provinces until March 17, 2020 (Fig. 1), and a significant correlation was found between frequency of anosmia and COVID-19 in various provinces (Spearman Coefficient: 0.87, $P < 0.001$, Fig. 2).

From the clinical point of view, 60.90% of the responders reported complete loss of sense of smell. The onset of anosmia was sudden in 76.24%, and 80.38% also reported some decrease in their sense of taste. The clinical findings are summarized in Table 1.

Approximately, 10.55% of the responders had a history of a trip out of their home town before the onset of their olfactory dysfunction, and about 1.1% were hospitalized

Fig. 1. Numerical scale of smell sensation at the time of filling questionnaire Zero (no sense of smell), 10 (full sense of smell)

Table 1. Summary of clinical manifestations and past medical history of participants

Clinical manifestation	No.	%
Flu or cold symptoms before anosmia	7608	75.56%
Headache (which needed pain reliever drug)	4903	48.69%
Nasal stiffness	4400	43.70%
Fever and chills	3764	37.38%
Sore throat	1948	19.35%
Prominent cough	1911	18.98%
Orbital (periorbital) pain	1898	18.85%
Facial fullness and sinus pain	1864	18.51%
Rhinorrhea	1574	15.63%
Dyspnea	1448	14.38%
Nasal irritation	1380	13.71%
Parosmia	1287	12.78%
Nasal pruritus	1083	10.76%
Otalgia	999	9.92%
Sneezing frequent	914	9.08%
Purulent nasal discharge	879	8.73%
Cheeks pain	452	4.49%
Unilateral facial palsy	52	0.52%
Past medical history		
History of hypothyroidism	1077	10.70%
History of asthma	612	6.08%
History of hypertension	428	4.25%
Previous sinus surgery or septorhinoplasty	266	2.64%
History of diabetes mellitus	199	1.98%
History of hyperthyroidism	158	1.57%
History of epilepsy	47	0.47%

No.: number

due to recent respiratory problems. From the family point of view, in 12.17% of the responders, one of the close relatives had a history of severe respiratory disease in recent days, and in 7.35% at least one of their family members was hospitalized due to respiratory problem. In 48.23% of responders, at least one of the family members reported a recent history of anosmia. At the time of the response to the questions, the duration of anosmia ranged from 0 (the same day of onset) to 30 days (11.33 ± 6.81 , median = 10.00). Use of a numerical scale which coded as 0 (no smell/taste, significantly decreased quality of life) to 10 (full smell/taste, normal quality of life) showed that a significant number of patients still had smell and taste problems at the time of responding to the questionnaire; however, some improvements could also be noted (Figs. 1 and

3). The quality of life was obviously affected due to olfactory dysfunction (Fig. 4).

Discussion

During March 2020, the number of patients with olfactory dysfunction was increased in different provinces of Iran, concurrent with COVID-19 epidemic. Thus, we decided to assess the prevalence of this olfactory dysfunction disorder by an online questionnaire in this population-based study. The results of this study showed a widespread olfactory dysfunction all over the country. Also, a significant linear correlation between prevalence of COVID-19 and olfactory impairment that was published online on March 27, 2020 (11). The recent outbreak of olfactory dysfunction following

Fig. 4. Numerical Scale of quality of life at the time of filling questionnaire. Zero (significantly decreased quality of life), 10 (normal quality of life)

flu-like symptoms (75%), higher incidence in women (71%), and a high incidence of anosmia in family members (48.23%) are suggestive of a postviral epidemic olfactory dysfunction in Iran. Although our study could not establish that COVID-19 was the definite cause of olfactory dysfunction, there are no other recent viral epidemics in Iran except COVID-19. Thus, as the COVID-19 pandemic rises in parallel with olfactory dysfunction, it can be suggested that these 2 are intimately linked. However, later studies in patients with definite diagnosis of COVID-19 showed that olfactory dysfunction had a considerable prevalence in these patients (12-14). For instance, a study on 417 COVID-19 patients was performed by Lechien et al and showed that 79.6% of COVID-19 patients had olfactory dysfunction (15). In addition, a study by Menni et al found that 59% of COVID-19 positive patients had loss of smell and taste as compared to 18% of COVID-19 negative patients (16). Moreover, Moein et al showed that 98% of patients with COVID-19 exhibited some smell dysfunction, of them 58% were either anosmic or severely microsmic (17). Based on these reports, Menni et al and Kaye et al suggested that olfactory dysfunction should be considered as a manifestation of COVID-19 (16, 18).

Common COVID-19 symptoms, such as fever, cough and dyspnea, were less common in participants with olfactory dysfunction compliant (87.9% vs 37.38%, 67.7% vs 18.98% and 18.6% vs 14.38%, respectively) and only about 1.1% of the study population was hospitalized due to respiratory problems recently.

In 2007, Suzuki et al detected Rhinovirus, Coronavirus, Parainfluenza virus, and Epstein-Barr virus in the nasal secretion of postviral olfactory disorders patients for the first time. Also, they suggested that the Rhinoviruses can target olfactory impairment through mechanisms other than nasal obstruction and that Rhinoviruses could induce different time courses of olfactory dysfunction (19).

Although the exact pathophysiology of postviral anosmia

is unclear, injury may happen at the level of the neuroepithelium of olfactory receptor cells in the nasal roof or in central olfactory routes. However, many studies have focused on the neuroepithelial changes in patients with post-viral olfactory dysfunction because of the accessibility of the olfactory cleft. Various animal studies explained that different viruses could damage central olfactory routes and other regions of the brain (20-23). It has been found that 36.4% of patients with COVID-19 had a variety of neurological symptoms involving central and peripheral nervous system. In addition, central nervous system findings were a more significant form of neurological damage in patients with COVID-19. (10) Thus as SARS-CoV-2 can reach the brain through the cribriform plate (24), anosmia or hyposmia in an uncomplicated COVID-19 case may also need to be considered.

There are some limitations to our study. As our data were collected via an online self-reported questionnaire, it was limited to the population who was literate and had access to the internet, personal computers or smart-phones, and were active in social networks. Another limitation of this study is that the participants had not been evaluated for SARS-CoV-2 test. As this was an online survey, the main goal was to confirm the outbreak of olfactory dysfunction during the COVID-19 epidemic.

Conclusion

We encountered an outbreak of olfactory dysfunction in Iran during the COVID-19 epidemic, which correlates with the number of patients infected with COVID-19 all over the country. As olfactory dysfunction can affect the quality of life in affected patients, it needs to be assessed worldwide by further clinical studies to find pathogenesis, prognosis, and any correlation between disease severity and olfactory dysfunction. Also, we recommend that sudden onset of anosmia be considered in routine work-up and screening for COVID-19 infection.

Appendix 1. Please take a few minutes to answer the following questions

N	Question	Response Options	
1	How did the onset of your olfactory dysfunction happen?	Slowly	Suddenly
2	Did you have olfactory dysfunction along with gustatory dysfunction?	Yes	No
3	Have you had any flu or cold symptoms (fever, rhinorrhea, cough, and sore throat) before anosmia?	Yes	No
4	Have you had a severe headache that needed a pain reliever drug?	Yes	No
5-7	Have you had fever and chills/ severe cough/ dyspnea before or during the olfactory dysfunction?	Yes	No
8	Did you smell the natural odors as unpleasant smells?	Yes	No
9	Rate your ability to smell during the first days of your olfactory dysfunction.	Line scale(0-10)	
10	Rate your ability to taste during the first days of your olfactory dysfunction.	Line scale(0-10)	
11	How many days have you had olfactory dysfunction?	0-30	
12	Rate your ability to smell right now (at the time of filling this questionnaire).	Line scale(0-10)	
13	Rate your ability to taste right now (at the time of filling this questionnaire).	Line scale(0-10)	
14	Did you use any medication for your olfactory dysfunction?	Yes	No
15	How was the pattern of your olfactory dysfunction?	Always/consistency	Sometimes/inconsistency
16	Did you get any nasal surgery such as previous sinus surgery or septorhinoplasty?	Yes	No
17	Rate the negative effect of your olfactory dysfunction on your quality of life.	Line scale(0-10)	
18	Which ones did you have along with your olfactory dysfunction?	Yes	No
	Nasal stiffness		
	Nasal pruritus		
	Nasal irritation		
	Sneezing (frequent)		
	Rhinorrhea		
	Purulent nasal discharge		
	Cheeks pain		
	Facial fullness and sinus pain		
	Orbital (periorbital) pain		
	Sore throat		
	Otalgia
