Abstract

Background: COVID-19 pandemic imposes a substantial medical and socioeconomic burden on health systems. The study aimed to estimate the direct inpatient costs of COVID-19 in Iran.

Methods: This is a Cost of Illness (COI) study with the bottom-up method. Provider perspective and prevalence approach were applied for cost identification. Data included inpatient charges and clinical characteristics of all COVID-19 cases (2015 patients) admitted to a teaching hospital during a financial year (March 2020 to February 2021). We extracted data from Hospital Information System (HIS) and applied the quantile regression to estimate determinant factors of COVID-19 inpatient cost using STATA software.

Results: 1026 (50.92%) of admitted COVID-19 patients were female, and 42.3% were older than 65 years. More than 82% of discharged COVID-19 patients in this study recovered. 189 (9.38%) patients admitted to ICUs. Length of Stay (LOS) for about 70% of admitted COVID-19 cases was 7 days or less. The Total Inpatient Charges (TIC) was 155,372,056,826 Rials (5,041,836 PPP USD). The median charge was 42,410,477 Rials, and Average Inpatient Charges (AIC) was 77,107,720±110,051,702 (2,461 PPP USD) per person. Drugs and supplies accounted for 37% of total inpatient charges. Basic insurance companies would pay more than 79% of total claims and the share of Out-of-Pocket Payments (OOP) was 7%. ICUs admission and LOS of more than 3 days are associated with higher costs across all percentiles of the cost distribution ($p<0.001$).

Conclusion: This study call attention to the substantial economic burden based on real-world data. According to the broad socioeconomic impacts of COVID-19 and also multiple components of COI study designs, conducting meta-analysis approaches is needed to combine results from independent studies.

Introduction

COVID-19 pandemic, a global threat for human life, afflicted millions of people one year after its abrupt beginning around the world (1, 2). The first confirmed case of COVID-19 in Iran was reported in Feb 2020 (3) and after that, the Iranian health system applied national and local quarantine, mass media education, rapid screening and diagnostic tests and equipped hospital settings for prevention

and treatment of confirmed cases. These broad strategies are required to mobilize human resources, reallocate financial resources and fund healthcare facilities against COVID-19 limitations. Analysis of real-world data about the impact of the COVID-19 pandemic on the health system's functions and goals will help to inform policymakers for better management of resources.

↑What is “already known” in this topic:

- COVID-19 as a recent global health threatening condition imposes socioeconomic burden to health systems.

→What this article adds:

- This study call attention to substantial economic burden of COVID-19 based on the real-world data.
- The study findings would inform policy makers for appropriate resources allocation to provide accessible and affordable health services.

The assessment of direct and indirect costs attributed to an illness would help health systems to determine economic burden, estimate budgets, conduct cost-effectiveness analysis and design financing and payment mechanisms such as Diagnosis Related Group (DRG) (4-7).

COI studies identify, measure, and value the direct, indirect and intangible cost of a disease or public health problem (7, 9). The direct cost of a disease includes resources consumed for hospital inpatient and outpatient care, nursing home care, hospice care, rehabilitation care, specialists' and other health professionals' care, diagnostic tests, prescription drugs, and medical supplies (8, 10). Inpatient cost gets a high share of health care expenditure for noncommunicable (11) and infectious conditions (12).

Study perspective in COI is vital and implies for whose lens we are looking at the cost of a condition. It determines the data that will be collected. Common perspectives for COI studies are government, insurer, provider, patients and societal perspectives. The societal perspective is comprehensive and includes all opportunity costs that an illness imposes on society (10).

COI studies for various respiratory diseases expanded over time. Trucchi et al. (13) in a retrospective study, tried to estimate the economic burden and hospital cost of influenza-like illness and lower respiratory tract infection in adults 50 or more years old in Italy over the six influenza epidemic seasons. They reported the mean cost of emergency hospitalization for Influenza-like illnesses and lower respiratory tract infections as €3353. Ghaffari Darab et al. (14) estimated both direct medical and indirect costs of treating COVID-19 from a societal perspective in Iran. Based on their results, COVID-19 cost about 28,240,025,968 Rials in a referral hospital from March to July 2020. Cleary et al., (15) assessed the cost-effectiveness of intensive care management for COVID-19 patients in South Africa.

Conducting COI studies for COVID-19 will provide findings for evidence-based resource allocation and compare components of health care cost. So, this study aimed to estimate the direct inpatient cost of COVID-19 in Iran.

Methods

Cost, Charges, and Payment in Hospital Costing

The concepts of cost, charge and payment are different but they may use wrongly as an alternative in hospital costing. Cost includes the value of resources a hospital consumes to provide a service. Charges are billed tariffs assigned by a hospital during service procedures. Payment is the money amounts that are paid by purchasers to the hospital (16). So, cost data indicate the provider's perspective. Charge data are simply more accessible than cost data, and if tariffs are determined really (based on true cost), the charge would be a proxy for cost data in hospital financial administration. On the other side, payment data estimate the COI from the purchaser's perspective. Comparison of the magnitude of cost, charge and payment reported in some indicators such as cost-to-charge ratios and payment-to-charge ratios (16, 17). We used charges data to estimate the direct inpatient cost of COVID-19 from the provider's perspective in a teaching hospital.

Study setting and design

The total number of hospitals in Iran in 2019 was 1020, including 146,217 hospital beds. Based on annals of hospital information and statistics from the ministry of health and medical education, teaching hospitals accounted for 25% of Iranian hospitals and 45% of Iranian hospital beds (18). This is a Cost of Illness (COI) study with a bottom-up method conducted at Bohlool Hospital affiliated with Gonabad University Medical Sciences, east Iran. This teaching hospital has 256 active inpatient beds and departments for emergency care, surgery, internal medicine, intensive care, gynecology, midwifery and obstetrics care, ENT, pediatrics, orthopedics, urology, neurosurgery, operation room, hemodialysis, radiology, para-clinic examination, and outpatient clinics. This hospital serves as a referral treatment center and teaching field for medicine students. From the beginning of the COVID-19 epidemic in Iran in Feb 2020, this center provided national treatment protocol to admitted COVID-19 patients. To estimate resources allocated to the treatment management of COVID-19 in the teaching hospital, we designed a COI study with a prevalence-based approach.

Sampling and data collection

All 2015 clinical confirmed COVID-19 cases that were admitted to the Bohlool hospital in one financial year from March 2020 to February 2021 were entered into the study. Data were collected in a retrospective design from hospital medical records through HIS. The data included cost and financial information, demographic characteristic, medical services and curative procedures for admitted COVID-19 cases. We applied the provider's perspective, so charge data were extracted from HIS over the first year after the COVID-19 pandemic.

Data management and analysis

Data were extracted from HIS, and primarily data management process and descriptive statistics analysis were done in Excel. Total Inpatient Cost (TIC) was calculated for each admitted COVID-19 case by summing up hoteling, nursing services, visit and consultation, drugs, laboratory test, x-ray, operation room and medical supplies and other items.

Average Inpatient Charges (AIC) estimated by:

$$\frac{\text{Total Inpatient Charges}}{\text{Total number of admitted cases}}$$

We applied quantile regression analysis using Stata 13.0 (Stata Corporation, Texas, USA) to estimate the effects of determinant factors on COVID-19 inpatient expenditure across the multiple quantiles of the expenditure distribution. The quantile regression is less sensitive to outliers and suitable for work on the highly skewed distribution of the dependent variable. So, it is a good alternative when the main assumptions of linear regression are not satisfied (19, 20). We used the case fatality rate to estimate the total admitted cases of COVID-19 in Iran. By multiplying the number of hospitalized cases by AIC, we estimated a national burden for total direct inpatient costs in Iran. For

international comparisons, all estimated costs were adjusted to current international dollars based on the World Bank's purchasing power parity (PPP) conversion factors (1 PPP\$ = 31328.95 Rials) (21).

Results

Demographic and Hospitalization Characteristics Profile

Of the 2015 patients studied, 1026 (50.92%) were female, and 42.3% of them were aged greater than 65 years. More than 82% of cases were discharged as healed. 189 (9.38) patients admitted to ICUs. LOS for About 78% of admitted COVID-19 cases was less than 8 days. Table 1

shows demographic characteristics of 2015 COVID-19 cases admitted to the teaching hospital during a year and the distribution of inpatient charges for each factor variable.

Direct Inpatient Cost

The TIC for 2015 admitted COVID-19 case was 155,372,056,826 Rials (4,959,376 PPP USD). The median cost was 42,410,477 Rials (1,354 PPP USD), and the mean (or AIC) was 77,107,720 (SD: 110,051,702) (2,461 PPP USD) per person. Drugs and supplies accounted for 37% of total inpatient charges. Figure 1 shows the proportion of each hospital cost items.

Fig. 1. The proportion of inpatient cost items for COVID-19 in the teaching hospital

Table 3. The share of financing agents for COVID-19 payment

Financing Agent	Payment (Rials)	Percent
Basic Insurance	124,390,031,567	79
Government Subsidy and Discount	15,795,112,851	10
Supplementary Insurance	5,782,059,178	4
Out of Pocket Payment	11,988,238,928	7
Total	157,955,442,524	100

Financing Agents

The amount of money in hospital claims for the financing agent was 157,955,442,524 Rials (5,041,836 PPP USD). Major financing agent was basic insurance companies that would pay more than 79% of total claims. The share of OOP in the financing of COVID-19 inpatient charges was 7%. (Table 2).

Table 3 summarizes the coefficient estimates and 95% confidence intervals for each of the five determinant factors. Among five determinant factors, ICU admission and LOS of more than 3 days are associated with higher costs across all percentiles of the cost distribution. Co-diagnosis were linked to higher costs among high-cost patients and death outcome were linked to higher costs among low-cost patients.

Discussion

The aim of the study was to determine the direct inpatient cost of COVID-19 in a teaching hospital and estimate a national burden for the Iranian health system. Based on demographic and hospitalization characteristics, 42.38% of the study population was aged above 65 years. 82.35% of COVID-19 cases admitted to the teaching hospital recovered and the case fatality rate was 12.58% (it means that

from every 100 admitted cases, 12.58 people died). Baigi et al (22) explored the epidemiological characteristics of COVID-19 in a major hospital in Tehran, Iran. They estimated the case fatality rate as 12.5% and 9.8% for men and women respectively. A similar study of the United States in-hospital mortality reported 13.6% (23). These differences might be associated with different impacts of sequential waves of COVID-19 because there is a difference in the length of the study period between these studies. Conducting meta-analysis approaches is needed to combine results from independent studies.

In this study, about 30% of patients had LOS for more than 7 days. A review of past studies showed LOS for COVID-19 was associated with demographic and clinical factors and varied substantially between health settings and countries (24). Of 2015 hospital admitted cases, 9.38% were admitted to an ICU. Regarding the pressing demand for ICU services during the COVID-19 pandemic, effective management of ICU procedures from admission to discharge is essential. Sadeghi et al (25) reported that 25.7% of COVID-19 patients were admitted to ICU in a teaching hospital in Tehran. In the study of the economic burden of hospitalized COVID-19 patients in the United States (23), Di Fuscoa et al. reported that 21.9% of hospitalized cases

were admitted to the ICU. In the comparison of COI studies conducted for COVID-19, we faced different study periods while treatment protocols have been varying over time, so different health service utilization indicators are possible.

The total TIC for 2015 hospital admitted COVID-19 case was 155,372,056,826 Rials (4,959,376 PPP USD). The median was 42,410,477 Rials (1,354 PPP USD), and the mean (or AIC) was 77,107,720 (2,461 PPP USD). In a similar study in Iran (14), Ghafari Darab et al reported 59,203,409 Rials as the mean cost per person. Nakhaei et al (26) estimated the total direct and indirect cost for 745 hospitalized patients with COVID-19 in Vali-e-Asr Hospital affiliated with Birjand University of Medical Sciences, Iran from March 2020 to July 2020. They reported the mean of total direct cost (including hospitalization cost, outpatients cost and direct nonmedical cost) as 3362.49 PPP\$. In the United States, median hospital charges and median hospital costs for hospitalized COVID-19 patients were reported at 43,986 and 12,046 respectively (23). Achonu et al. (27) reported the cost for controlling a SARS outbreak in a teaching hospital over an 8-week period as 12 million dollars in Canada. The study by A. Khan et al., (28) in Saudi Arabia estimated direct medical costs of hospitalized COVID-19 patients at 42,704.49 SAR in general wards and 79,418.30 for ICU admitted cases. They concluded the mean direct medical cost per COVID-19 patient was not significantly different from a MERS-CoV case but a high number of COVID-19 infections led to a larger amount of total direct medical cost of COVID-19. The comparison between costing results should be based on several components of COI design such as different perspectives, costing methods, cost types, etc.

In this study, drugs and supplies accounted for the biggest share (37%) of the total inpatient charge of COVID-19 in a teaching hospital. In the study conducted in Shiraz province (14), drugs included 28% of the direct medical cost for hospitalized COVID-19 cases. Cost-effective drug protocols will play a significant role in controlling health spending through treatment management of COVID-19 and other infectious diseases.

Universal Health Coverage (UHC) and other social protection plans emphasize low OOP for ensuring equitable access to medical care for all population groups (29, 30). Also, the Price-demand elasticity in an emergency condition for medical care is low (31), so financial protection of patients against COVID-19 is a high priority (32). Furthermore, El-Khatib et al., (33) reported a positive association between high OOP and COVID-19 mortality. Our findings

showed basic social insurance packages covered about 80% of the total payment for inpatient care for COVID-19 and the share of OOP was just 7% during the first year after the epidemic.

The quantile regression model indicated that ICUs admission and LOS of more than 3 days are associated with higher costs across all percentiles of the cost distribution. In a similar study in Iran (14), inpatient cost for COVID-19 cases in ICUs was four times greater than in other units. In a recent study in South Africa, Cleary et al. (15) conducted a cost-effectiveness analysis of intensive care for hospitalized COVID-19 patients. In this study cost per admission of severe and critical COVID-19 patients in general wards was 75,127 ZAR and increased to 103,030 ZAR for patients who used ICUs. Taheri et al. (34) reviewed the cost-accounting records of all surviving patients discharged with LOS of 4 days or more from a university hospital in the United States. They concluded LOS has minimal impact on the cost of hospital admission.

This study encountered some limitations. We used charge data as a proxy for COVID-19 inpatient costs in a teaching hospital. Charges are formal tariffs assigned by a hospital to patients' records. These tariffs may not depict the true cost incurred over the COVID-19 treatment. Also, some cost items such as cost for overhead departments and personnel protection equipment ignored in this study. Our study setting was one referral teaching hospital, for addressing this limitation, we chose a longer study time frame than other similar studies to capture diverse cases of several waves of COVID-19.

National burden of COVID-19 direct inpatient cost

We used the case fatality rate to estimate the total admitted cases of COVID-19 in Iran. The total number of COVID-19 death divided by the hospital case fatality rate. So, 595,840 hospitalized cases were estimated for 12 months in Iran (Table 4). After that, by multiplying the number of hospitalized cases by AIC, we estimated the total direct inpatient cost in Iran for 12 months would be about 1,466,498.682 PPP USD (equals 0.138 % of Iranian GDP).

Conclusion

This study call attention to the recent global health-threatening condition in term of socioeconomic burden. The results indicated a substantial economic burden for COVID-19 based on real-world data. These findings would inform policymakers for appropriate resource allocation to

provide accessible and affordable health services. According to the broad socio-economic impacts of COVID-19 and also multiple components of COI study designs, conducting meta-analysis approaches is needed to combine results from independent studies.

Abbreviation

COI: Cost of Illness; HIS: Hospital Information System; DAMA: Discharge Against Medical Advice; LOS: Length of Stay; TIC: Total Inpatient Charges; AIC: Average Inpatient Charges; OOP: Out-of-Pocket Payments; DRG: Diagnosis Related Group.

Ethics approval

We gained approval from the ethics committee of Gonabad University of Medical Science (ethical code: IR.GMU.REC.1398.186).

Acknowledgment

The social development and health promotion research center supported the study. The authors would like to acknowledge and thank the Clinical Research Development Unit of Bohloul hospital in Gonabad University of Medical Sciences for their contribution to this research. Special thanks to Azam Zanganeh at the information technology department of the hospital.

Conflict of Interests

The authors declare that they have no competing interests.
